On one of our websites, we have integrated a custom authentication token that is generated by the application on the user's first request to the website. This token was chosen as a simpler authentication mechanism than a database of IP addresses. However, it is not a true authentication mechanism - merely a mechanism to allow us to identify who the user is. We are using this authentication mechanism in all of our APIs and so the website is less secure. If someone has a list of IP addresses, then an attacker can perform a man-in-the-middle attack by intercepting an API request and then responding as the user. However, with a custom authentication token, the website will generate a new token after each request, so the user will not be identified. I believe that the standard approach to dealing with this is to allow the website to be less secure. However, I do not understand why this is the case, since the risk of a man-in-the-middle attack is eliminated. Any suggestions as to how to deal with this scenario will be greatly appreciated. A: Is there a risk? Not really. The risk of an attacker man-in-the-middle is present in every case where the server (or client) is in control of any security component. If you want to minimize the risk of an attacker getting in, use SSL. That way the data cannot be eavesdropped on before it is sent and/or after it is received. There's no special authentication mechanism which does not pose a risk. An infrequently updated blog for various articles and news items, particularly about the law, human rights, and the developing world. Wednesday, October 1, 2012 One Soldier, Two Wars The US military has just announced that one of its soldiers was killed in Afghanistan on Saturday. The man, from Nevada, was one of two soldiers on an attack helicopter when they were shot down. The helicopter was part of a combat mission that failed to spot a Taliban fighter laying in the open near Kandahar. With any luck, the other soldier survived, but it seems that on Saturday a Taliban fighter shot down the helicopter. It crashed in the Khakrez District of Kandahar, and after

A sensitive and specific high-performance liquid chromatographic assay for ifosfamide, cyclophosphamide and dacarbazine in human plasma and urine was developed using ultraviolet detection. The method involves extraction into ethyl acetate, evaporation and reconstitution of the residue in mobile phase. The detection limits of the assay were 0.15 microg ml(-1) for ifosfamide and dacarbazine, 0.8 microg ml(-1) for cyclophosphamide and 0.2 microg ml(-1) for the internal standard (2-methylhydrazino-5- 2d92ce491b
